Introduction

In this notebook, we use Amazon Textract and Google Vision to provide a quick way of extracting text/tables from an image of a page.

Intended use: The intended use of this notebook is to quickly prototype. You should expect to modify the code in this notebook to suit your usecase.

Preparation: At a minimum, set a working folder, and make sure to add your API keys for both Textract and Google Vision. To do so, please follow the steps outlined here: https://github.com/MikeJGiordano/OCR_History/blob/main/ReadMe.md

This notebook contains four parts:

- 1. Unmodified image OCR. This is intended to quickly detect text from a single image. a. There is then an option to run one or both OCR tools on a whole folder.
- 2. Image preprocessing. This routine helps you to quickly preprocess a single image (adjust contrast, split image, etc). a. If you are satisfied with the preprocessing routine, it will give you the option to preprocess a whole folder.
- 3. Image preprocessing with text extraction. This runs the image modification from part 2 into the text detection from part 1.
- 4. Image preprocessing with table extraction from Textract. This uses the image modification from part 2 to extract a table using Textract.

Program Setup

import preprocess as pp

filename = "NYT.png"

There are 5 steps, marked A-E.

A: Import packages

In []: import io import json import os # if you don't have these packages use any package manager to install # you can install all packages at once using the provided requirements.txt file import cv2 import boto3 from google.cloud import vision import matplotlib.pyplot as plt import numpy as np import pandas as pd import tqdm as tq from PIL import Image, ImageDraw from textractor import Textractor from textractor.visualizers.entitylist import EntityList from textractor.data.constants import TextractFeatures, Direction, DirectionalFinderType # note: the following py file, you'll have to download

B: Please set your working directories here

In []: # please set the path to the folder containing your images here input folder = "images/" # please set the path to a desired output folder here output_folder = "output/"

In []: | # set the filename to your image here

D: Please authenticate Google Cloud

C: Please set your main input file here

For help with Google Cloud, see https://github.com/MikeJGiordano/OCR_History/blob/main/Setup_Google_Cloud.md

os.environ['GOOGLE_APPLICATION_CREDENTIALS'] = 'ServiceAccountToken.json'

In []: #Authenticate Google Cloud here:

client = vision.ImageAnnotatorClient()

E: Please authenticate Amazon Textract

For help with Amazon Textract, see https://github.com/MikeJGiordano/OCR_History/blob/main/Setup_AWS_Root.md

In []: #Authenticate AWS Textract in the console/terminal

In []: # plot the image, save .json outputs pp.process_content(filename,

Part 1: Basic text extraction

input folder, output folder, show_image=True,

use_google_vision=True,

use_textract=False, verbose=True) You can use the next cell to get text and JSON files for the entire input folder through Google Vision, Textract, or both. # Batch process all images in the input folder, save text and JSON outputs to the output folder

Often, it helps to preprocess an image. Common routines are:

Part 2: Preprocess images

pp.batch ocr(input folder,

1. Adjusting contrast or brightness 2. Converting to grayscale

output_folder,

use_google_vision=False,

use_textract=False)

- 3. Cropping 4. Erasing margins
- 5. Splitting images
- 1. Applying points 1-4 2. Preprocessing and splitting the image

In []: # set the filename to your image here filename = "1888_Page_161.png"

We now provide two examples:

Example 1: Full image

In []: #The next cell will apply the default preprocess settings to your image.

pp.preprocess_image(filename,

#If you are unsatisfied with those settings, it will provide instructions on how to make changes. In []: #Preprocess a single image.

**pp.default); Example 2: Split image

In []: # set the filename to your split image here

pp.default['left_margin_percent'] = 30

input folder, output_folder,

In []: #The next cell will apply the default preprocess settings to your image. #If you are unsatisfied with those settings, it will provide instructions on how to make changes.

split_filename = "126.png"

pp.default['top_margin_percent'] = 5 In []: #Preprocess a split image. pp.preprocess_image(split_filename, input folder,

Part 3: Preprocessed Text Extraction **Example 1: Full image**

In []: # using the above processing, the folder of modified images is located at: modified_images = "output/modified_images/"

output_folder, **pp.default);

Modification alters the name of the file to be: modified filename = 'modified ' + filename

In []: # plot the image, save .json outputs pp.process content(modified filename, modified_images, output folder, show image = True, use_google_vision=False, use_textract=True, verbose=True)

modified_1_split = 'modified_1_' + split_filename modified_2_split = 'modified_2_' + split_filename

Example 2: Split image

pp.process_content(modified_1_split, modified images, output_folder,

verbose=True)

modified_images, output folder,

In []: # Modification splits the file into two and renames them:

show_image = True, use google vision=True, use_textract=False,

In []: # plot the images, save .json and .txt outputs

pp.process_content(modified_2_split,

pp.batch_ocr(modified_images,

show_image = False, use_google_vision=False, use textract=False, verbose=False) You can use the next cell to get text and JSON files for the entire folder of modified images through Google Vision, Textract, or both.

In []: # Batch process all images in the modified folder, save .json outputs to the output folder

Setup

output folder,

use_google_vision=False,

use_textract=False)

Part 4: Textract Table Extraction

In []: extractor = Textractor(profile_name="default")

Please specify the image you want to extract a table from.

Modification alters the name of the file to be:

using the above processing, the folder of modified images is located at:

Initialize Textractor client, modify region if required

modified_images = "output/modified_images/"

modified_filename = 'modified_' + filename

Extract the tables

modified filename,

modified_images, output_folder);

pp.extract_table(extractor,
